

(a) Where does order freedom enter?

Schedule type

Current state at t

Transition rule

State at $t + 1$

Sequential:

$B = 1$

(one eligible position)

one active position

commit one position
(no ranking needed)

Block-parallel:

$B > 1$

multiple eligible positions
($B = 32$, schematic)

active block: eligible positions

rank, then commit
selected positions

Confidence-first

$$c_i = p_{\theta}(\tilde{x}_i | x_t)$$

Random

$$u_i \sim U(0, 1)$$

Entropy-first

$$h_i = H[p_{\theta}(x_i | x_t)]$$

(b) Policy rankings can reverse as k grows

SCHEMATIC • NOT TO SCALE
